# October 17, 2022

# Temporary Importation of Fludarabine Phosphate Injection USP from Canada to Address Drug Shortage

Dear Healthcare Professional:

Due to the current critical shortage of Fludarabine Phosphate Injection USP products in the United States (U.S.) market, Accord Healthcare Inc., USA (Accord) is coordinating with the U.S. Food and Drug Administration (FDA) to temporarily import unapproved Fludarabine Phosphate Injection USP [50 mg/2 mL (25 mg/mL)] into the U.S. market. The Fludarabine Phosphate Injection USP from Accord Healthcare Inc., is marketed in Canada

Effective immediately, and during this temporary period of shortage, Accord will offer the following presentation of Fludarabine Phosphate Injection USP from Canada to the U.S. market:

Product Name & Description	Strength/Presentation	Dosage Form	Package size	NDC
Fludarabine Phosphate Injection, USP	50 mg/2 mL (25 mg/mL)	Injectable	2 mL, Single Dose, Clear Glass Vial with Orange "Flip-Off" Seal	16729-131-30

The vial and carton labels will display the text used and approved for marketing the products in Canada with both English and French translations. It is important to note that there are differences in the format and content of the labeling as mentioned below between the US approved product and Accord's Fludarabine Phosphate Injection USP. Specifically, the preparation and stability of this product differs from the U.S. version. Please see the product comparison table at the end of this letter.

Table 1. Key differences in Fludarabine Phosphate Injection USP

The barcode on the imported product label may not register accurately on the U.S. scanning systems. Institutions should manually input the imported product information into their systems and confirm that the barcode, if scanned, provides correct information. Alternative procedures should be followed to assure that the correct drug product is being used and administered to individual patients.

In addition, the packaging of the imported product does not include serialization information. Accord's Fludarabine Phosphate Injection USP does not meet the Drug Supply Chain Security Act (DSCSA) requirements for the Interoperable Exchange of Information for Tracing of Human, Finished Prescription Drugs.

Fludarabine Phosphate Injection USP is available only by prescription in the U.S. Please refer to the package insert for the FDA-approved Fludarabine Phosphate Injection USP drug product for full prescribing information

**To report adverse events** associated with the use of this product, Healthcare providers should report to Accord Healthcare Inc at 1-866-941-7875.

**To report quality problems, or if you have any questions about** the information contained in this letter or the use of Accord's Fludarabine Phosphate Injection USP, please contact Accord Healthcare Inc at 1-866-941-7875 or at accord usa@accord-healthcare.com.

Adverse events or quality problems experienced with the use of this product may also be reported to the FDA's MedWatch Adverse Event Reporting Program either online, by regular mail, or by fax:

- Complete and submit the report **Online**: www.fda.gov/medwatch/report.htm
- **Regular mail or Fax**: Download form <a href="www.fda.gov/MedWatch/getforms.htm">www.fda.gov/MedWatch/getforms.htm</a> or call 1-800-332-1088 to request a reporting form, then complete and return to the address on the pre-addressed form or submit by fax to 1-800-FDA-0178 (1-800-332-0178).

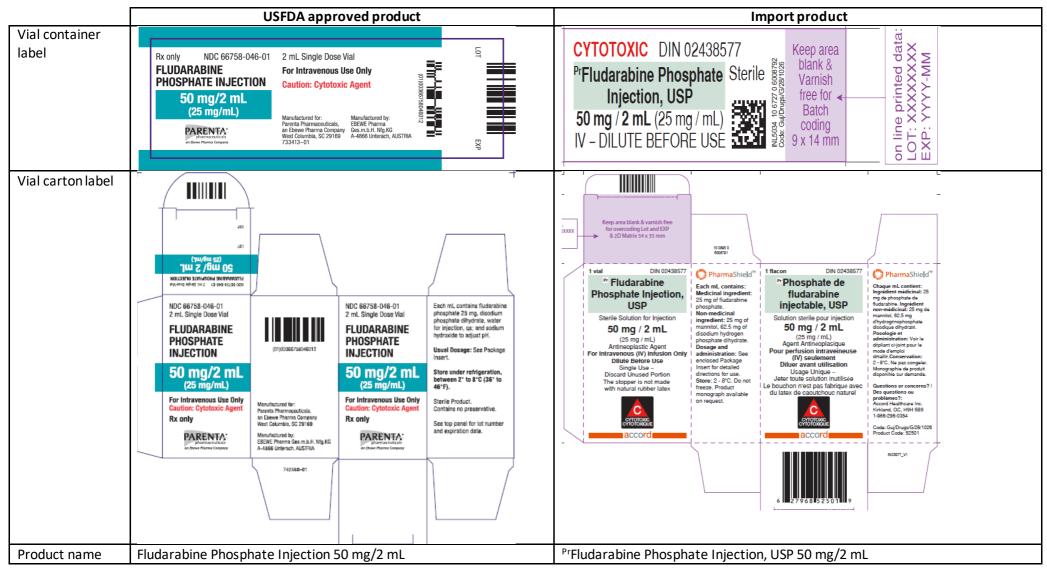

To place an order, please contact Accord at <u>csaccord@intaspharma.com</u>.

We remain at your disposal to answer any questions you may have about our product and provide more information if needed.

Sincerely,

Sabita Nair, RAC, ASQ-CPGP Vice President-Regulatory Affairs Accord Healthcare, Inc.

		PHOSPHATE INJECTION, USP can induce a response as early as the first week of

The effect of chronic administration of fludarabine phosphate on the central nervous system is unknown; however, patients have received the recommended dose for up to 15 courses of therapy.

Fludarabine phosphate may reduce the ability to drive or use mechanical equipment, since fatigue, weakness, visual disturbances, confusion, agitation and seizures have been observed.

#### 5.2 Bone Marrow Suppression

Severe bone suppression, notably marrow anemia. thrombocytopenia and neutropenia, has been reported in patients treated with fludarabine phosphate. In a Phase I study in adult solid tumor patients, the median time to nadir counts was 13 days (range, 3 to 25 days) for granulocytes and 16 days (range, 2 to 32 days) for platelets. Most patients had hematologic impairment at baseline either as a result of disease or as a result of prior myelosuppressive therapy. Cumulative myelosuppression may be seen. While chemotherapy-induced myelosuppression is often reversible, administration of Fludarabine Phosphate Injection requires careful hematologic monitoring.

Several instances of trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia, sometimes resulting in death, have been reported in adult patients. The duration of clinically significant cytopenia in the reported cases has ranged from approximately 2 months to approximately 1 year. These episodes have occurred both in previously treated or untreated patients.

#### 5.3 Autoimmune Reactions

Instances of life-threatening and sometimes fatal autoimmune phenomena such as hemolytic anemia, autoimmune thrombocytopenia/thrombocytopenic purpura (ITP), Evans syndrome, and acquired hemophilia have been reported to occur after one or more cycles of treatment with fludarabine phosphate in patients with or without a previous history of autoimmune hemolytic

#### Import product

treatment, precautions should be taken in those patients at risk of developing this complication.

#### Gastrointestinal

In clinical trials with oral fludarabine phosphate, nausea/vomiting and/or diarrhea were reported in approximately 38% of patients. In most cases, the severity was mild to moderate (WHO toxicity grading). Only a small percentage of patients, approximately 1 % with nausea/vomiting and 5% with diarrhea, required therapy. Patients with prolonged, clinically relevant, nausea/vomiting and diarrhea should be closely monitored to avoid dehydration.

## Hematologic

In patients with an impaired state of health, FLUDARABINE PHOSPHATE INJECTION, USP should be given with caution and after careful risk/benefit consideration. This applies especially to patients with severe impairment of bone marrow function (thrombocytopenia, anemia, and/or granulocytopenia), immunodeficiency or with a history of opportunistic infection. Prophylactic treatment should be considered in patients at increased risk of developing opportunistic infections (see **ADVERSE REACTIONS**).

Severe bone marrow suppression, notably thrombocytopenia, anemia, leukopenia and neutropenia, may occur with administration of FLUDARABINE PHOSPHATE INJECTION, USP and requires careful hematologic monitoring. In a Phase I study in solid tumor patients, the median time to nadir counts was 13 days (range, 3- 25 days) for granulocytes and 16 days (range, 2-32 days) for platelets. Most patients had hematologic impairment at baseline either as a result of disease or as a result of prior myelosuppressive therapy. Cumulative myelosuppression may be seen. While chemotherapy-induced myelosuppression is often reversible, administration of FLUDARABINE PHOSPHATE INJECTION, USP requires careful hematologic monitoring.

Several instances of trilineage bone marrow hypoplasia or aplasia resulting in pancytopenia, sometimes resulting in death, have been reported in adult patients. The duration of clinically significant cytopenia in the cases reported has

anemia or a positive Coombs' test and who may or may not be in remission from their disease. Steroids may or may not be effective in controlling these hemolytic episodes. The majority of patients rechallenged with fludarabine phosphate developed a recurrence in the hemolytic process. The mechanism(s) which predispose patients to the development of this complication has not been identified. Patients undergoing treatment with Fludarabine Phosphate Injection should be evaluated and closely monitored for hemolysis. Discontinuation of therapy with Fludarabine Phosphate Injection is recommended in case of hemolysis.

#### 5.4 Transfusion Associated Graft-Versus-Host Disease

Transfusion-associated graft-versus-host disease has been observed after transfusion of non-irradiated blood in fludarabine phosphate treated patients. Fatal outcome as a consequence of this disease has been reported. Therefore, to minimize the risk of transfusion-associated graft-versus-host disease, patients who require blood transfusion and who are undergoing, or who have received, treatment with Fludarabine Phosphate Injection should receive irradiated blood only.

# 5.5 Pulmonary Toxicity

In a clinical investigation using fludarabine phosphate in combination with pentostatin (deoxycoformycin) for the treatment of refractory chronic lymphocytic leukemia (CLL) in adults, there was an unacceptably high incidence of fatal pulmonary toxicity. Therefore, the use of Fludarabine Phosphate Injection in combination with pentostatin is not recommended.

# 5.6 Pregnancy

Pregnancy Category D

Based on its mechanism of action, fludarabine phosphate can cause fetal harm when administered to a pregnant woman. There are no adequate and well-controlled studies of fludarabine phosphate injection in pregnant women, Fludarabine phosphate was

### Import product

ranged from approximately 2 months to approximately 1 year. These episodes have occurred in both previously treated and untreated patients.

Instances of life-threatening and sometimes fatal autoimmune phenomena (e.g. autoimmune hemolytic anemia, autoimmune thrombocytopenia, thrombocytopenic purpura, pemphigus, acquired hemophilia and Evans' syndrome) have been reported to occur during or after treatment with fludarabine phosphate in patients with or without a previous history of autoimmune processes or a positive Coombs' test and who may or may not be in remission from their disease.

Steroids may or may not be effective in controlling these hemolytic episodes. One study was performed with 31 patients with hemolytic anemia related to the administration of fludarabine phosphate. Since the majority (90%) of these patients rechallenged with fludarabine phosphate developed a recurrence in the hemolytic process, rechallenge with FLUDARABINE PHOSPHATE INJECTION, USP should be avoided. The mechanisms which predispose patients to the development of this complication have not been identified. Patients undergoing treatment with FLUDARABINE PHOSPHATE INJECTION, USP should be evaluated and closely monitored for signs of autoimmune hemolytic anemia (a decline in hemoglobin linked with hemolysis and a positive Coombs' test). Discontinuation of therapy with FLUDARABINE PHOSPHATE INJECTION, USP is recommended in the event of hemolysis. The transfusion of irradiated blood and the administration of corticosteroids are the most common treatment measures for autoimmune hemolytic anemia.

# **Hepatic/Biliary/Pancreatic**

No data are available concerning the use of fludarabine phosphate in patients with hepatic impairment. In this group of patients, FLUDARABINE PHOSPHATE INJECTION, USP should be used with caution and administered if the perceived benefit outweighs any potential risk.

# <u>Immune</u>

Transfusion-associated graft-versus-host disease (reaction by the transfused immunocompetent lymphocytes to the host) has been observed after

embryolethal and teratogenic in rats and rabbits. If this drug is used during pregnancy, or if the patient becomes pregnant while taking this drug, the patient should be apprised of the potential hazard to the fetus. Women of childbearing potential should be advised to avoid becoming pregnant. [see Use in Specific Populations (8.1)]

#### 5.7 Male Fertility and Reproductive Outcomes

Males with female sexual partners of childbearing potential should use contraception during and after cessation of fludarabine phosphate therapy. Fludarabine phosphate may damage testicular tissue and spermatozoa. Possible sperm DNA damage raises concerns about loss of fertility and genetic abnormalities in fetuses. The duration of this effect is uncertain. [see Nonclinical Toxicology (13.1)]

#### 5.8 Tumor Lysis

Tumor lysis syndrome has been associated with fludarabine phosphate treatment. This syndrome has been reported in CLL patients with large tumor burdens. Since fludarabine phosphate can induce a response as early as the first week of treatment, precautions should be taken in those patients at risk of developing this complication.

# 5.9 Renal Impairment

Fludarabine Phosphate Injection must be administered cautiously in patients with renal impairment. The total body clearance of 2-fluoro-ara-A has been shown to be directly correlated with creatinine clearance. Patients with creatinine clearance 30 to 79 mL/min should have their fludarabine phosphate dose reduced and be monitored closely for excessive toxicity. Fludarabine phosphate should not be administered to patients with creatinine clearance less than 30 mL/min. [see Dosage and Administration (2.2) and Use in Specific Populations (8.6)]

In patients aged 65 years or older, creatinine clearance should be measured before start of treatment.

# Import product

transfusion of nonirradiated blood in patients treated with fludarabine phosphate. Fatal outcome as a consequence of this disease has been reported with a high frequency. Therefore, to minimize the risk of transfusion-associated graft-versus-host disease, patients who require blood transfusion and who are undergoing or who have received treatment with FLUDARABINE PHOSPHATE INJECTION, USP should receive irradiated blood only.

#### Neurologic

Administration of fludarabine phosphate can be associated with leukoencephalopathy (LE), acute toxic leukoencephalopathy (ATL), or posterior reversible encephalopathy syndrome (PRES)/ reversible posterior leukoencephalopathy syndrome (RPLS).

LE, ATL or PRES/RPLS may occur:

- at the recommended dose, most commonly
  - when fludarabine phosphate is given following, or in combination with, medications known to be associated with LE, ATL or PRES/RPLS, or
  - when fludarabine phosphate is given in patients with cranial or total body irradiation, Graft versus Host Disease, renal impairment, or following Hematopoietic Stem Cell Transplantation.
- at doses higher than the recommended dose.

When high doses of fludarabine phosphate were administered in dose-ranging studies in acute leukemia patients, a syndrome with delayed onset, characterized by blindness, coma, and death was identified. Symptoms appeared from 21 to 60 days post dosing (however, in post marketing experience, cases of neurotoxicity have been reported to occur both earlier and later than seen in clinical trials). Demyelination, especially of the occipital cortex of the brain was noted. The majority of these cases occurred in patients treated intravenously with doses approximately four times greater (96 mg/m²/day for 5-7 days) than the recommended dose. Thirteen of 36 patients (36.1%) who received fludarabine phosphate at high doses ( $\geq$  96 mg/m²/day for 5 to 7 days per course) developed severe neurotoxicity, while only one of 443 patients (0.2%) who received the drug at low doses ( $\leq$  40 mg/m²/day for 5 days per course) developed the toxicity. In patients treated at doses in the range of the

USFDA approved product	Import product
5.10 Vaccination	dose recommended for CLL, Lg-NHL, severe central nervous system toxicity occurred rarely (coma, seizures and agitation) or uncommonly (confusion).
During and after treatment with Fludarabine Phosphate Injection, vaccination with live vaccines should be avoided.	LE, ATL or PRES/RPLS symptoms may include headache, nausea and vomiting, seizures, visual disturbances such as vision loss, altered sensorium, and focal neurological deficits. Additional effects may include optic neuritis, and papillitis, confusion, somnolence, agitation, paraparesis/quadriparesis, muscle spasticity, incontinence, and coma.
	The onset of the neurologic symptoms can be delayed and may occur after discontinuation of fludarabine. Late-occurring encephalopathy has been reported up to 4.8 years following fludarabine.
	LE/ ATL/ PRES/RPLS may be irreversible, life-threatening, or fatal.
	The effect of chronic administration of fludarabine phosphate on the central nervous system is unknown. In some studies, however, patients tolerated the recommended dose, for relatively long treatment periods (up to 26 courses of therapy).
	Periodic neurological assessments are recommended. Whenever LE, ATL or PRES/RPLS is suspected, FLUDARABINE PHOSPHATE INJECTION, USP treatment should be stopped. Patients should be monitored and should undergo brain imaging, preferably utilizing MRI. If the diagnosis is confirmed, FLUDARABINE PHOSPHATE INJECTION, USP therapy should be permanently discontinued.
	Renal The total body clearance of the principal plasma metabolite 2F-ara-A shows a correlation with creatinine clearance, indicating the importance of the renal excretion pathway for the elimination of the compound. Patients with reduced renal function demonstrated an increased total body exposure (AUC of 2F-ara-A). Limited clinical data are available in patients with impairment of renal function (creatinine clearance below 70 mL/min). Therefore, if renal impairment is clinically suspected, or in patients over the age of 70 years, creatinine clearance should be measured. If creatinine clearance is between 30 and 70

USFDA approved product	Import product
	mL/min, the dose should be reduced by up to 50% and close hematological monitoring should be used to assess toxicity. FLUDARABINE PHOSPHATE INJECTION, USP treatment is contraindicated, if creatinine clearance is < 30 mL/min. (See <b>DOSAGE AND ADMINISTRATION</b> ).
	Sexual Function/Reproduction Preclinical toxicology studies in mice, rats and dogs have demonstrated doserelated adverse effects on the male reproductive system. Observations consisted of a decrease in mean testicular weights in dogs and degeneration and necrosis of spermatogenic epithelium of the testes in mice, rats and dogs. The possible adverse effects on fertility in males and females in humans have not been adequately evaluated. Therefore, it is recommended that men and women of child-bearing potential take contraceptive measures during FLUDARABINE PHOSPHATE INJECTION, USP therapy, and for at least 6 months after the cessation of FLUDARABINE PHOSPHATE INJECTION, USP therapy.
	Skin The worsening or flare-up of pre-existing skin cancer lesions, as well as new onset of skin cancer, has been reported to occur in patients during or after intravenous (i.v.) fludarabine phosphate therapy.
	Special Populations Pregnant Women: There are very limited data of fludarabine phosphate use in pregnant women in the first trimester: one newborn has been described with absent bilateral radii and normal thumbs, thrombocytopenia, fossa ovalis aneurysm and a small patent ductus arteriosus. Early pregnancy loss has been reported in fludarabine phosphate monotherapy as well as in combination therapy. Premature delivery has been reported.
	FLUDARABINE PHOSPHATE INJECTION, USP should not be used during pregnancy unless clearly necessary (e.g., life-threatening situation, no alternative safer treatment available without compromising the therapeutic benefit, treatment cannot be avoided). It has the potential to cause fetal harm. Prescribers may only consider it to be used if the potential benefits justify the

 USFDA approved product	Import product
	potential risks to the fetus. Women of childbearing potential must be apprised of the potential hazard to the fetus.
	Women should avoid becoming pregnant while on FLUDARABINE PHOSPHATE INJECTION, USP therapy. Women of childbearing potential or fertile males must take effective contraceptive measures during and at least for 6 months after cessation of therapy.
	Nursing Women: Breast-feeding should not be initiated during FLUDARABINE PHOSPHATE INJECTION, USP treatment. Nursing women should discontinue breastfeeding.
	It is not known whether this drug is excreted in human milk. There is evidence from preclinical data that after intravenous administration to rats that fludarabine phosphate and/or metabolites transfer from maternal blood to milk.
	<b>Pediatrics:</b> The safety and effectiveness of fludarabine phosphate in children have not been established.
	Geriatrics (> 75 years of age): Since there are limited data for the use of fludarabine phosphate in elderly persons (> 75 years), caution should be exercised with the administration of FLUDARABINE PHOSPHATE INJECTION, USP in these patients. The total body clearance of the principal plasma metabolite 2F-ara-A shows a correlation with creatinine clearance, indicating the importance of the renal excretion pathway for the elimination of the compound. Patients with reduced kidney function demonstrated an increased total body exposure (AUC of 2F-ara-A). Limited clinical data are available in patients with impairment of renal function (creatinine clearance below 70 mL/min). Since renal impairment is frequently present in patients over the age of 70 years, creatinine clearance should be measured. If creatinine clearance is between 30 and 70 mL/min, the dose should be reduced by up to 50%, and close hematologic monitoring should be used to assess toxicity. FLUDARABINE PHOSPHATE INJECTION, USP treatment is contraindicated if creatinine clearance is < 30 mL/min. (See DOSAGE AND ADMINISTRATION).

Adverse Reactions	6 ADVERSE REACTIONS  Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice. Very common adverse reactions include myelosuppression (neutropenia, thrombocytopenia and anemia), fever and chills, fatigue, weakness, infection, pneumonia, cough, nausea, vomiting and diarrhea. Other commonly reported events include malaise, mucositis, and anorexia. Serious opportunistic infections have occurred in CLL patients treated with fludarabine phosphate. The most frequently reported adverse reactions and those reactions which are more clearly related to the drug are arranged below according to body system.  6.1 Hematopoietic Systems  Hematologic events (neutropenia, thrombocytopenia, and/or	thrombocytopenia), pneumonia, cough, Other commonly reneuropathy, visual of Serious opportunist fludarabine phosphahave been reported.  The table below renewed the causal relationships and the causal relationships are considered.	adverse ever opression leading to fever, fatig eported ever disturbance tic infection ate. ## Import product

#### **Post-Market Adverse Reaction**

The following adverse reactions are based on post-marketing data regardless of the causal relationship with fludarabine phosphate.

**Blood and lymphatic disorders**: pancytopenia, myelosuppression, neutropenia, thrombocytopenia, anemia, cytopenia, tri-lineage bone marrow aplasia

Cardiac disorders: edema, heart failure, arrhythmia

**Eye disorders:** blindness, optic neuritis, optic neuropathy, eye hemorrhage including retinal

**Gastrointestinal disorders**: anorexia

General disorders and administrative conditions: chills

Genitourinary disorders (initial PI)/Metabolism and nutritional disorders: hematuria (context of TLS), hypocalcemia (context of TLS), hyperphosphatemia (context of TLS), hyperuricemia, renal failure (context of TLS), urate crystalluria (context of TLS), metabolic acidosis (context of TLS), hyperkalemia (context of TLS)

**Hepatobiliary disorders**: hepatic enzymes abnormal, pancreatic enzymes abnormal

**Immune system disorders**: transfusion-related GVHD, thrombocytopenic purpura, Evans syndrome, pemphigus, autoimmune hemolytic anemia, acquired hemophilia

**Infections and infestations**: opportunistic infections, herpes zoster virus, Epstein-Barr virus, latent viral reactivation, progressive multifocal leucoencephalopathy, human polyomavirus JC virus (context of PML), disease transformation CLL

Use in Specific	8.1 Pregnancy			Pregnant Women:
Populations	Based on its mechanism of action, fludarabine phosphate can cause fetal harm when administered to a pregnant woman. There are no adequate and well-controlled studies of Fludarabine Phosphate			There are very limited data of fludarabine phosphate use in pregnant women in the first trimester: one newborn has been described with absent bilateral radii and normal thumbs, thrombocytopenia, fossa ovalis aneurysm and a small patent ductus arteriosus. Early pregnancy loss has been reported in fludarabine
	Injection in pregnant women. In rats, repeated intravenous doses of fludarabine phosphate at 2.4 times and 7.2 times the recommended human IV dose (25 mg/m²) administered during organogenesis			phosphate monotherapy as well as in combination therapy. Premature delivery has been reported.  Page 18 of 20

caused an increase in resorptions, skeletal and visceral malformations (cleft palate, exencephaly, and fetal vertebrae deformities) and decreased fetal body weights. Maternal toxicity was not apparent at 2.4 times the human IV dose, and was limited to slight body weight decreases at 7.2 times the human IV dose. In rabbits, repeated intravenous doses of fludarabine phosphate at 3.8 times the human IV dose administered during organogenesis increased embryo and fetal lethality as indicated by increased resorptions and a decrease in live fetuses. A significant increase in malformations including cleft palate, hydrocephaly, adactyly, brachydactyly, fusions of the digits, diaphragmatic hernia, heart/great vessel defects, and vertebrae/rib anomalies were seen in all dose levels (≥ 0.5 times the human IV dose). If this drug is used during pregnancy, or if the patient becomes pregnant while taking this drug, the patient should be apprised of the potential hazard to the fetus. Women of childbearing potential should be advised to avoid becoming pregnant.

# 8.3 Nursing Mothers

It is not known whether fludarabine phosphate is excreted in human milk. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions including tumorigenicity in nursing infants, a decision should be made to discontinue nursing or discontinue the drug, taking into account the importance of the drug for the mother.

#### 8.4 Pediatric Use

Data submitted to the FDA was insufficient to establish efficacy in any childhood malignancy.

Fludarabine phosphate was evaluated in 62 pediatric patients (median age 10, range 1 to 21) with refractory acute leukemia (45 patients) or solid tumors (17 patients). Limited pharmacokinetic data for fludarabine phosphate are available in children (ages 1 to 21 years). When fludarabine phosphate was administered as a loading dose over 10 minutes immediately followed by a 5-day continuous infusion, steady-state conditions were reached early.

#### Import product

FLUDARABINE PHOSPHATE INJECTION, USP should not be used during pregnancy unless clearly necessary (e.g., life-threatening situation, no alternative safer treatment available without compromising the therapeutic benefit, treatment cannot be avoided). It has the potential to cause fetal harm. Prescribers may only consider it to be used if the potential benefits justify the potential risks to the fetus. Women of childbearing potential must be apprised of the potential hazard to the fetus.

Women should avoid becoming pregnant while on FLUDARABINE PHOSPHATE INJECTION, USP therapy. Women of childbearing potential or fertile males must take effective contraceptive measures during and at least for 6 months after cessation of therapy.

#### **Nursing Women:**

Breast-feeding should not be initiated during FLUDARABINE PHOSPHATE INJECTION, USP treatment. Nursing women should discontinue breastfeeding. It is not known whether this drug is excreted in human milk. There is evidence from preclinical data that after intravenous administration to rats that fludarabine phosphate and/or metabolites transfer from maternal blood to milk.

**Pediatrics:** The safety and effectiveness of fludarabine phosphate in children have not been established.

**Geriatrics (> 75 years of age):** Since there are limited data for the use of fludarabine phosphate in elderly persons (> 75 years), caution should be exercised with the administration of FLUDARABINE PHOSPHATE INJECTION, USP in these patients. The total body clearance of the principal plasma metabolite 2F-ara-A shows a correlation with creatinine clearance, indicating the importance of the renal excretion pathway for the elimination of the compound. Patients with reduced kidney function demonstrated an increased total body exposure (AUC of 2F-ara-A). Limited clinical data are available in patients with impairment of renal function (creatinine clearance below 70 mL/min). Since renal impairment is frequently present in patients over the age of 70 years, creatinine clearance should be measured. If creatinine clearance is between 30 and 70 mL/min, the dose should be reduced by up to 50%, and close hematologic

USFDA approved product	Import product
	monitoring should be used to assess toxicity. FLUDARABINE PHOSPHATE
The fludarabine phosphate regimen tested for pediatric lymphocytic	INJECTION, USP treatment is contraindicated if creatinine clearance is < 30
leukemia (ALL) patients was a loading bolus of 10.5 mg/m²/day	mL/min. (See <b>DOSAGE AND ADMINISTRATION</b> ).
followed by a continuous infusion of 30.5 mg/m²/day for 5 days. In 12	
pediatric patients with solid tumors, dose-limiting myelosuppression	
was observed with a loading dose of 8 mg/m²/day followed by a	
continuous infusion of 23.5 mg/m²/day for 5 days. The maximum	
tolerated dose was a loading dose of 7 mg/m²/day followed by a	
continuous infusion of 20 mg/m²/day for 5 days. Treatment toxicity	
included bone marrow suppression. Platelet counts appeared to be	
more sensitive to the effects of fludarabine phosphate than	
hemoglobin and white blood cell counts. Other adverse events	
included fever, chills, asthenia, rash, nausea, vomiting, diarrhea, and	
infection. There were no reported occurrences of peripheral	
neuropathy or pulmonary hypersensitivity reaction.	
8.6 Patients with Renal Impairment	
The total body clearance of the principal metabolite 2-fluoro-ara-A	
correlated with the creatinine clearance, indicating the importance of	
the renal excretion pathway for the elimination of the drug. Renal	
clearance represents approximately 40% of the total body clearance.	
Patients with creatinine clearance 30 to 79 mL/min should have their	
fludarabine phosphate dose reduced and be monitored closely for	
excessive toxicity. Due to insufficient data, fludarabine phosphate	
should not be administered to patients with creatinine clearance less	
than 30 mL/min [see Dosage and Administration (2.2), Warnings and	
Precautions (5.9)].
